

# Before airflow era → Schedule

→ Bash Script

→ Cron Job

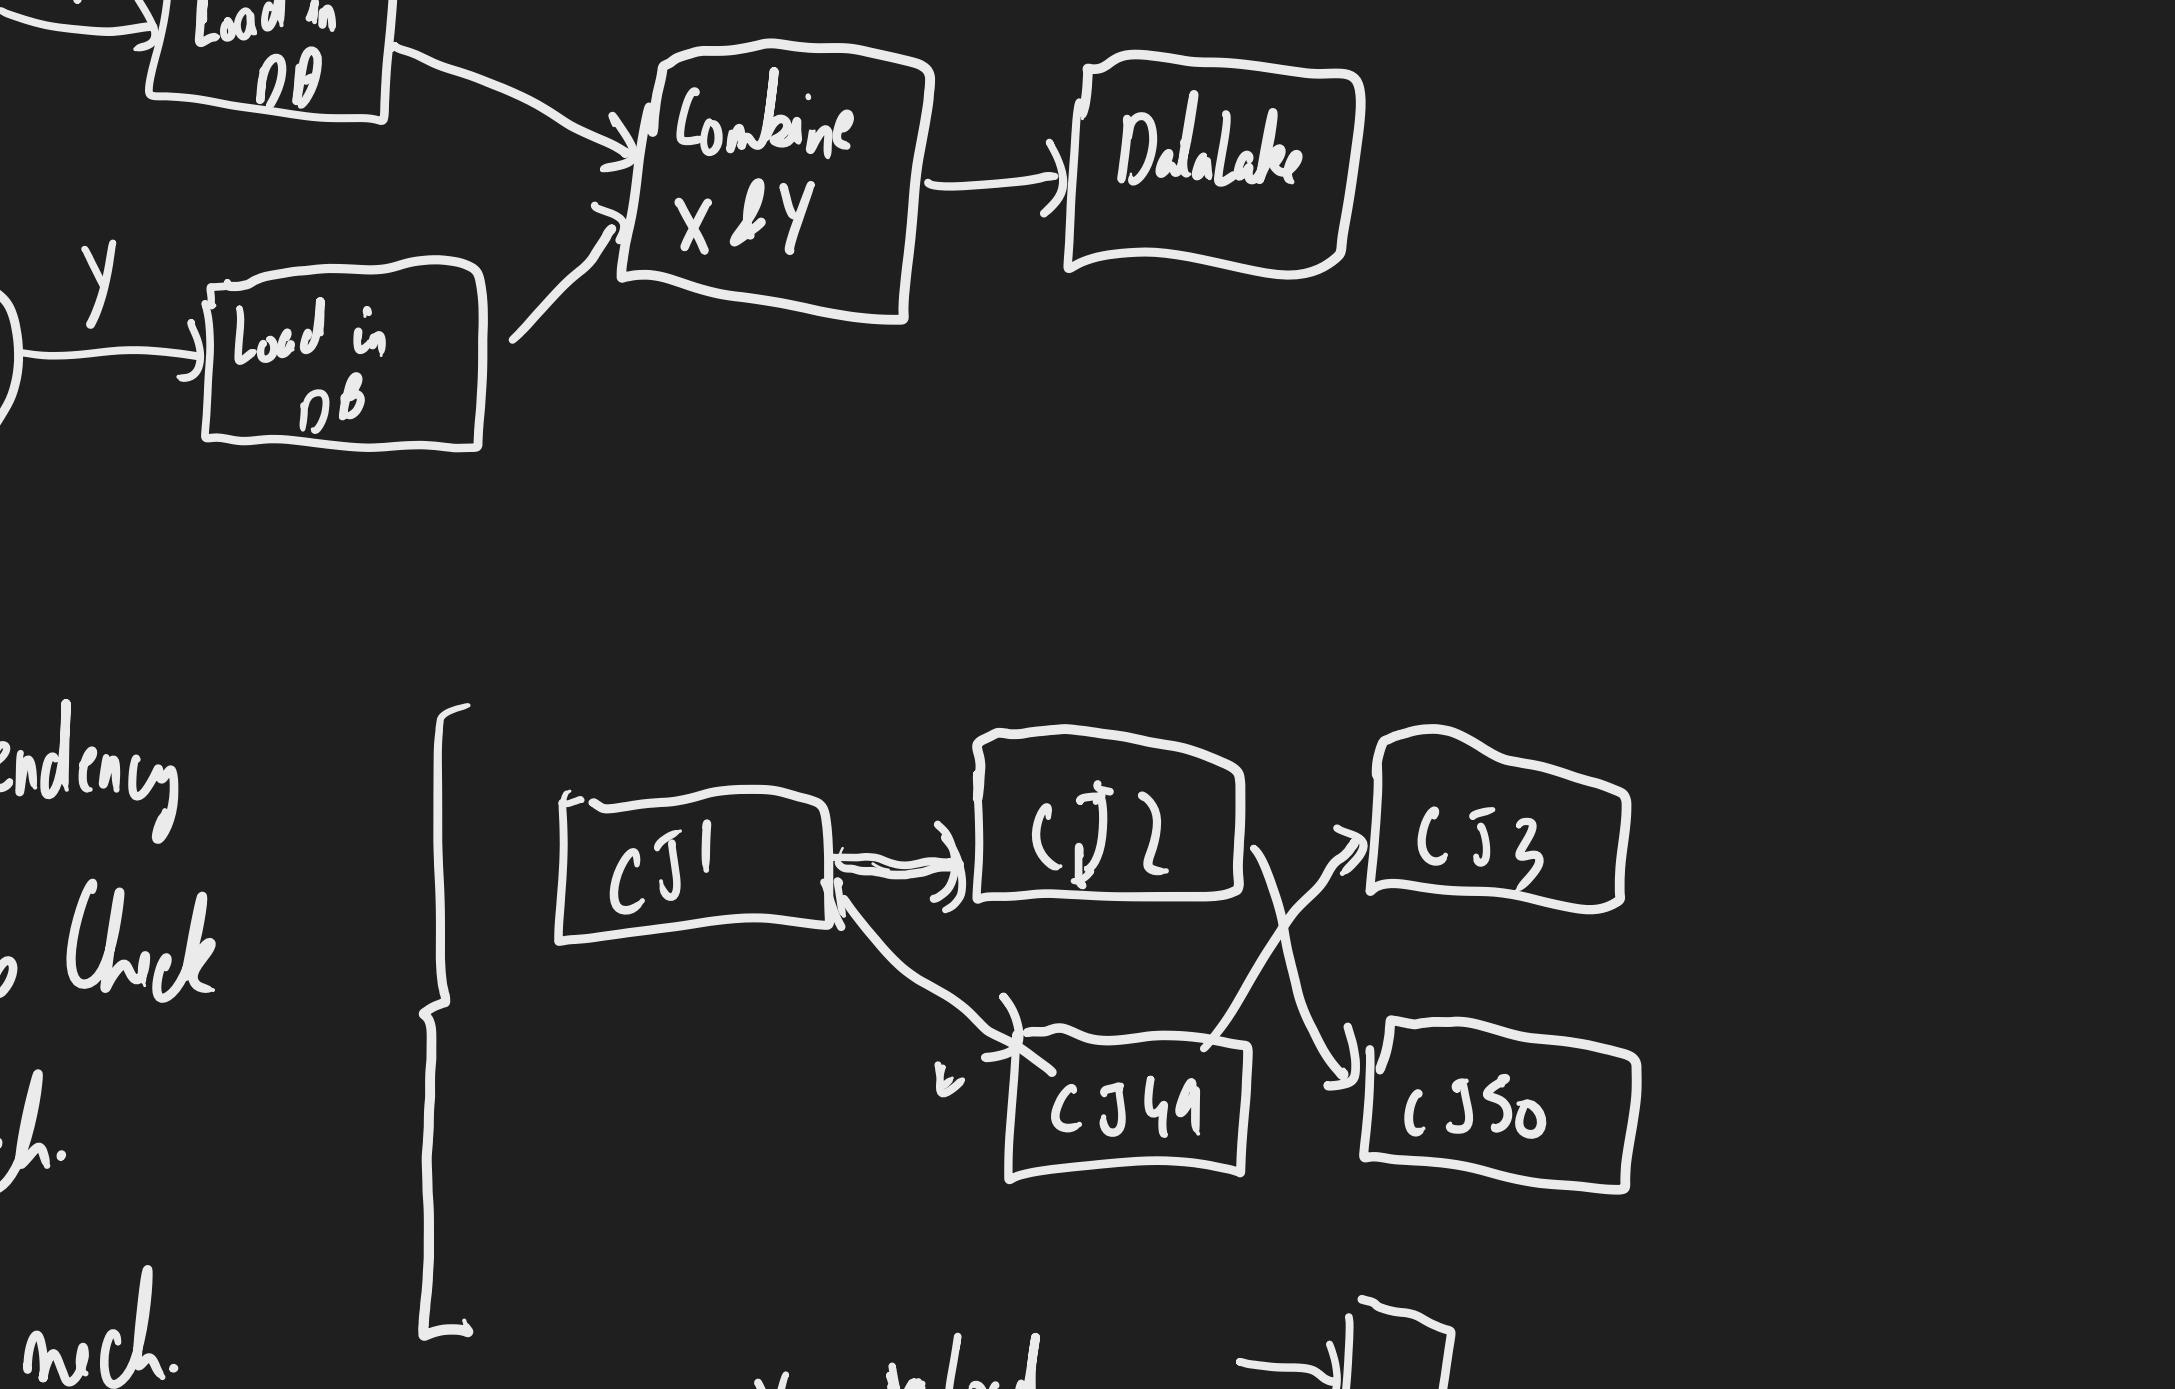

→ Python Code

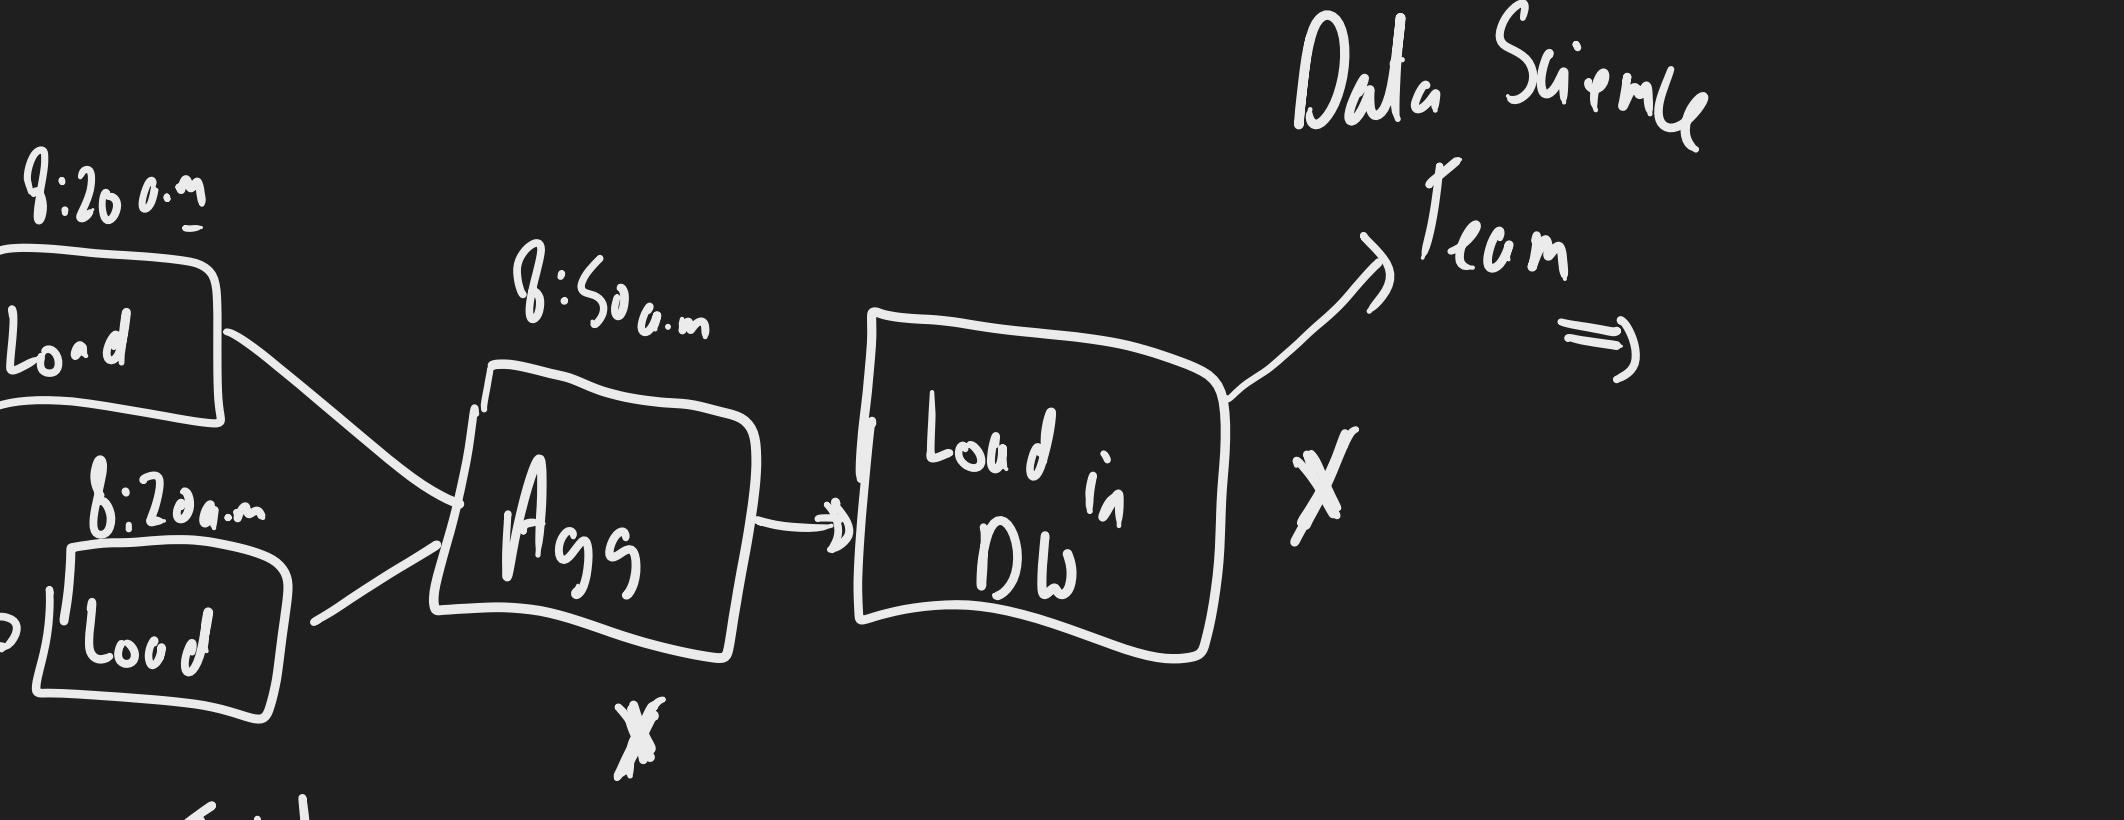

① Getting data from API, website (Extract)

② Dumping into AWS S3 (Load)

→ Bash, Cron Job, Python Code

Snip up 50 cron jobs

→ Inter dependency  
→ Job Status Check

→ Abort mech.

→ Re-run mech.

→ high Graphs

→ Load

→ Job

Data Science

→ Tcom

→ Monitoring: Job Status, view the previous jobs

→ Manage Failure: alerts on failure, retries, timeouts

→ Dependencies: check upstream data, run job2 only after job1.

→ Backfill: rerun the historic jobs

→ Scalability: Centralized System to manage the jobs

→ Deployment: version control orchestration system

Logs all the previous

jobs

# Technical Terms of Airflow:-

→ Task: It's the smallest unit of Job.

→ DAG: Directed Acyclic Graph

→ Sub-DAG: Subgraph of a DAG

→ Cyclic: Cycle in DAG

→ Job: Composed DAG

→ Not a DAG: Contains cycle

→ Scheduler: Triggers & schedules workflow and submits task to the executor.

→ Executor: Runs the tasks/jobs provided by scheduler.

→ Worker: Runs the tasks (machines)

→ Web-server: User Interface to inspect, trigger, debug the DAG/tasks.

→ Metadata Store: Stores info about DAG & tasks state.

(queue, on add, running, completed, failed)

→ DAG folder: This is directory where all the DAG's

code is persisted, read by scheduler and also

by the executor.

→ Frontend: WebServer (backend)

→ Scheduler: Manages DAGs

→ Executor: Runs tasks

→ Workers: Machines that run tasks

→ Metadata DB: Stores info about DAG & tasks state.

(queue, on add, running, completed, failed)

→ DAG: Directed Acyclic Graph

→ Sub-DAG: Subgraph of a DAG

→ Cyclic: Cycle in DAG

→ Job: Composed DAG

→ Not a DAG: Contains cycle

→ Scheduler: Triggers & schedules workflow and submits task to the executor.

→ Executor: Runs the tasks/jobs provided by scheduler.
